Q2860053 Read the passage carefully and answer the questions given below it:

Lactose intolerance is very common. People with lactose intolerance experience digestive problems when they eat dairy, which can have a negative effect on one's quality of life.

Lactose intolerance is a digestive disorder caused by the inability to digest lactose, the main carbohydrate in dairy products. It can cause various symptoms, including bloating, diarrhoea and abdominal cramps. People with lactose intolerance don't make enough of the enzyme lactase, which is needed to digest lactose. Lactose is a disaccharide, meaning that it consists of two sugars. It is made up of one molecule each of the simple sugar's glucose and galactose.

The lactase enzyme is needed to break lactose down into glucose and galactose, which can then be absorbed into the bloodstream and used for energy. Without sufficient lactase, lactose moves through your gut undigested and causes digestive symptoms. Lactose is also found in breast milk, and almost everyone is born with the ability to digest it. It is very rare to see lactose intolerance in children under the age of five. Currently, about 75% of the world's population is lactose intolerant.

There are two main types of lactose intolerance, which have different causes. Primary lactose intolerance is the most common. It is caused by a decrease in lactase production with age, so that lactose becomes poorly absorbed. This form of lactose intolerance may be partially caused by genes, because it's more common in some populations than others.

Population studies have estimated that lactose intolerance affects 5–17% of Europeans, around 44% of Americans and 60–80% of Africans and Asians. Secondary lactose intolerance is rare. It is caused by illness, such as a stomach bug or a more serious issue like celiac disease. This is because inflammation in the gut wall can lead to a temporary decline in lactase production.
